(54) Ink jet recording head and ink jet recording apparatus.

(57) In an ink jet recording device having an ink tank integrated type jet recording head (10) and a carriage (20) for mounting the head thereon, good electrical connection is obtained by constituting so that the electrical pad (13) of the connecting terminal (10a) of the recording head and the electrical pad (24) of the connecting terminal (20a) of the carriage are connected to each other while rubbing them one to one. Further, also by specifying the arrangement position of the positioning member, more accurate electrical conduction is effected and also breaking of the positioning member is prevented, thereby providing an ink jet recording device having high reliability in both aspects of recording and durability.

front surface of the recording head 101, particularly the upper part of 101b being forwarded greatly before the constant position after mounting. Then, a great space is required in front of the carriage. However, when good ink discharging is considered, since the interval between the recording head and the recording paper is designed to be 3.0 mm or less, and therefore it has been found to be difficult to take such constitution. Also, even if mounting may be effected at the home position, because great mutual interference with the cap cannot be avoided, such inconvenience as deformation of cap, etc. has been found to occur.

SUMMARY OF THE INVENTION

The present invention has been accomplished in view of these technical tasks of the prior art and the findings by the present inventors. Shortly speaking, an object of the present invention is to provide a recording head capable of effecting electrical connection in connecting the connecting terminals without damaging terminals and which can also scrape off the protective film provided on the terminal surface by mutual rubbing of the terminals with each other, and capable of positioning surely the recording head simultaneously with mounting completion of the recording head and a member for mounting of recording head and a recording head mounting method and an ink jet recording device.

Another object of the present invention is to provide a tank integrated type recording head which can accurately position an ink tank integrated recording head as the ink jet recording head onto the carriage of an ink jet recording device, to provide a carriage which can more surely hold said recording head and to provide an ink jet recording device having a recording head which can be accurately held under the desired state relative to within the main body of the device and a carriage. Another object of the present invention is to provide a constitution which can elongate the life of the positioning portion of said head itself which is detachable and the cap within the main body.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The present invention is described below by referring to a plurality of embodiments, but the present invention is not limited by these but includes many modified embodiments, provided that the object of the present invention can be accomplished.

The present invention is a constitution which can perform positioning of the recording head and the carriage with good precision, and with such constitution, accurate positioning of the ink discharge port, and accurate positioning capable of joining pads as unit elements of electrical connecting terminals while rubbing with each other at one to one can be done.

In the following, the respective embodiments are to be described in detail.

[First Embodiment]

This embodiment is an ink jet recording head having a discharge port for discharging ink and an energy generation means for generating energy for discharging ink, which is detachable relative to the mounting means for mounting the recording head onto the recording head of ink jet recording means, characterized in that the recording head has a surface having the discharge port provided thereon, an electrical connecting terminal provided on a surface forming a specific angle with respect to the surface and a rotation center portion in attachment and detachment relative to the mounting means of the recording head, the center axis of the rotation center portion is substantially parallel to the surface where the discharge port is provided and the surface where the connecting terminal is provided, with its position being made on the side opposed to the connecting terminal with respect to the surface where the discharge port is provided and outside the range where the discharge port is provided, and on the discharge port side relative to the connecting terminal near the surface side where the discharge port is provided.

Also, this embodiment is an ink jet recording device, comprising an ink jet recording head having a discharge port for discharging ink and energy generation means for generating energy for discharging ink, wherein the recording head has a surface having the discharge port provided thereon, an electrical connecting terminal provided on a

surface forming a specific angle with respect to the surface and a rotation center portion in attachment and detachment relative to the mounting means of the recording head, the center axis of the rotation center portion is substantially parallel to the surface where the discharge port is provided and the surface where the connecting terminal is provided, with its position being made on the side opposed to the connecting terminal with respect to the surface where the discharge port is provided and outside the range where the discharge port is provided, and on the discharge port side relative to the connecting terminal near the surface side where the discharge port is provided and a mounting means having a site to be engaged to the rotation center for mounting the recording head.

Further, this embodiment is a method for mounting a recording head having a discharge port for discharging ink, an energy generation means for generating the energy for discharge of the ink through the discharge port and an electrical connecting terminal provided on a surface forming a specific angle with respect to the surface where the discharge port is provided, characterized in that the recording head is mounted by engaging the rotation center portion having a center axis in parallel to both the surface where the discharge port is provided and the surface where the connecting terminal is provided and located on the side opposed to the connecting terminal with respect to the surface where the discharge port is provided, outside of the range where the discharge port is provided and on the discharge port side relative to the connecting terminal near the surface side where the discharge port is provided, to the site corresponding to the mounting means with the rotation center portion as the center.

Referring now to Figs. 3 through Fig. 8B, this embodiment is described specifically and in detail.

Fig. 3 is a schematic perspective view of appearance showing the principal part of the recording device. Fig. 4 is a schematic perspective view of the recording head according to the embodiment of the present invention as viewed from the bottom side, and Fig. 5A is a schematic perspective view according to this embodiment, and Fig. 5B is a schematic plan view of the carriage of this embodiment as viewed from above.

First, in Fig. 1 the carriage 20 as the mounting means having the recording head 10 mounted thereon moves along the paper delivery roller 60 as guided by the guide shaft 40. The constitution is made such that the recording head 10 discharges ink toward the surface of the recording paper P as the recording medium, and forms an image with the attached ink droplets, thereby performing recording. 30 is the discharge restoration means located at the home position of the carriage 20. The

discharge restoration means is constituted of a cap 31 comprising an elastic material such as rubber, etc. provided for protecting the discharge port by covering over the discharge port and also preventing fixing of ink by prevention of drying of the discharge port vicinity including the discharge port, and a suction pump 33 communicated to the cap 31 through an elastic tube 32. By sucking ink and/or air through the discharge port by reducing the pressure internally of the cap 31 with the pump 33, the discharging state of ink can be made good. The carriage 20 is located at the home position as the non recording position except when the recording head 10 performs recording, so that the discharge port may be protected there with the cap 31. And, the constitution is made so that attachment and detachment of the recording head 10 may be performed necessarily at the home position.

This can be done by controlling electrically the motor (not shown) for driving the carriage.

Next, by referring to Fig. 4, the constitution of the recording head 10 is described. In these Figures, the recording head 10 of the ink tank integration type is equipped with a recording head element 10C provided with an electrothermal transducer not shown as the energy generation means for generating thermal energy as the energy to be utilized for discharging of ink. For such recording head element, otherwise a piezoelectric element, etc. can be also employed as the energy generation means. However, the constitution by use of the electrothermal transducer as mentioned above having the advantages of simple constitution, lowered production cost and possibility of high densification may be preferably utilized.

10a is a connecting thermal for transmitting the recording signal (electrical signal), 10b a guide pin which becomes the rotation center of the recording head 1 during attachment and detachment relative to the carriage 20 by fitting to the carriage 20 as described below. The recording head element 10C is provided with a plurality of ink discharge ports 10d on the front surface. The connecting terminal 10a is provided with a concavity 10f which is a portion recessed by about 1 to 2 mm toward inside with longitudinal length $X = 35$ mm and lateral length $Y = 10$ mm for preventing contamination with ink, etc. and deformation, etc. of the connecting terminal 10a by touching with hands during handling. Behind the recording head is provided a fixing hook 10g (see Fig. 6A) for fixing the recording head through engagement with the nail portion of the carriage 20.

Referring now to Figs. 5A and 5B, the constitution of the carriage 20 is described. In these Figures, 20a is the connecting terminal bonded to the connecting terminal 10a of the recording head 10,

20b the fitting portion fitted (engaged) to the guide pin 10b of the recording head 10, 20c the elastic member for giving an adequate pressure contact force (20 to 50 g per one terminal) during bonding of the connecting terminals 10a and 20a, for which chloroprene rubber, urethane rubber, molybdene rubber, etc. may be used as preferable material for having optimum modulus of elasticity. 22 is a plate spring provided to taking balance with the pressure forces of connecting terminals 10a and 20a, and has the hop-up function during dismantling of the head as described below. 23 is engaged with the fixing hook 10g of the recording head 10 to fix and hold the recording head 10. 50 is a flexible cable for transmitting electrical signals from the recording control section not shown to the connecting terminal 20a of the carriage.

Here, although the description of the connecting terminal 20a is different between Figs. 5A and 5B, this is done for simplification of the drawings, and the specific constitutions should be understood from the following description.

The mounting method of the recording head in the constitution as described above is described in detail by referring to Figs. 6A to 6D.

Fig. 6A shows the state of mounting initiation state, Fig. 6B the first state in the course of mounting, Fig. 6C the second state in the course of mounting and the Fig. 6D the state on completion of mounting.

First, as shown in Fig. 6A, when the recording head 10 is placed on the carriage 20, the guide pin 10b of the recording head 10 and the carriage 10 at the bottom of the head 10 are guided by the guide surface 20h and the tip end 20t of the lock lever 20i, and moves in the direction A in the Figure by the weight of the recording head 1. Next, as shown in Fig. 6B, when the guide pin 10b is fitted into the fitting portion 20b, the rear end portion of the recording head 10 comes off from the lock lever 20i, to rotate the guide pin 10b in the direction C with the guide pin 10b as the center, whereby the fixing hook 10g comes against the lock lever as shown in Fig. 6C. Next, when the rear end of the recording head 10 is compulsorily pushed down in direction D, the discharge port surface from the state as shown in Fig. 6C contacts little by little from its upper portion the elastic portion of the cap 31. Then, the connecting terminals 10a and 20a contact successively from the discharge outlet side, until finally the fixing hook 10g is hooked by the nail portion 23 of the lock lever 20i to become the state held by fixing as shown in Fig. 6D, whereby the connecting terminals 10a and 20a are correctly connected electrically and mechanically.

In the constitution capable of performing the actuation as described above, since the guide pin 10b, namely the rotation center of the recording

head 10 is provided within the range AR upwardly of the position corresponding to the cap and in front of the connecting terminal, the front surface (namely discharge port) and the cap 31 of the recording head element 10c, and the connecting terminals 10a and 20a are adequately contacted or connected with each other without interference with other portions.

Further, by slight rubbing mutually between the connecting terminals during mounting of the recording head 10, foreign matters existing on the terminal surface can be also shaven off or scraped off to give the action of effecting surely electrical connection.

This manner is described in more detail by referring to Figs. 7A to 7E and Figs. 8A and 8B. Figs. 7A through 7E show the manner in which the connecting terminals are bonded to each other. Figs. 8A and 8B are schematic illustrations partially enlarged of one of a plurality of electrode pads of connecting terminal, showing the states at the beginning of contact and on completion of connection.

The plural number of electrode pads 13 of the connecting terminal 10a of the recording head 10 of this embodiment are made of lead frame of metal, etc., with the contact points being made flat. The plural number of electrode pads 24 of the connecting terminal 20a of the carriage 20 are worked into semispherical projected shapes by application of plating to the terminal on the flexible cable 50. Corresponding to the mounting actuation of the recording head, the electrode pads from the discharge port side will contact from the state in Fig. 7A as shown in Fig. 7B, and successively as shown in Fig. 7C. In transferring from Figs. 7B to 7E, the pads are rubbed mutually one to one to maintain good electrical contact.

The pressure contact force at the contact point of the pad is controlled through deformation of the elastic member 20c, whereby superfluous contact force can be absorbed to give adequate pressure contact force. When mounting of the recording head is completed, as shown in Fig. 7E, the position of the connecting terminal 20a of the carriage is positioned lower than the position in Fig. 5A, whereby the pressure contact force is applied upwardly with the elastic member 20c. Such pressure contact force is balanced with the forces of the nail 23 and the fitting portion 20b of the carriage. Further, connection of the terminal is described in detail by referring to Figs. 8A and 8B. In Figs. 8A and 8B, I shows the contact position of the electrode pad 12 at the beginning of contact, and J the contact position of the electrode pads 13, 24 under the final state. Through the slippage k between the contact points, even when foreign matters may be adhered on the contact point terminal surface, they

can be scraped off to effect sure electrical connection. For connection as describe above ($k > 0$) to be effected, the constitution is required to be made such that the rotation center as the standard for rotation should be positioned with a predetermined distance in the direction of the normal line 13-2 of the contact portion of the electrode pad 13 of the recording head from the tangential line 13-1 of the contact portion, and also the electrical pad 24 of the carriage 20 should be dislocated ($m > 0$) when the head 10 is mounted.

Next, the method for dismantling the recording head 10 is to be described.

First, when the lock lever 20i is moved by pressing in the direction EJ in Fig. 6B as described above, the fixing hook 10g is disengaged from the nail 23 to release fixing of the recording head. Then, by the plate spring 22 provided for taking balance with the connecting terminals 10a and 20a, the rear portion of the recording head is hopped up through elastic force, and can be readily taken out.

Further, in the above-described embodiment of the present invention, the ink discharge port 10d, the electrical connecting terminal 10f are all provided on substantially one straight line in the recording head element 10c so as to hold readily the positional relationships of the respective elements with high precision. Also, in the present embodiment, further the above elements are provided on one end side where the recording head is located, and further the cap is located on the above straight line in the home position. According to this constitution, the positioning member for carriage and electrical connecting terminals can be arranged on one side of the recording head and the carriage, whereby an extremely advantageous constitution in aspect of practical armoring such as withdrawing of flexible cable, etc. is given, and also unsure capping due to positional slippage can be prevented to make the probability of breaking of the recording head and the cap accompanied with mounting actuation of the recording head very lower.

As described above, according to the mounting method of the first embodiment of the present invention, there is no breaking by way of rubbing of connecting terminals than is necessary and the recording head will receive no bad influence from outside, and also, even if foreign matters may be attached on the terminal surface of the recording head, they can be removed to effect mounting of the recording head onto the correct position of the carriage with a force enough to obtain electrical connection.

Also, attachment and detachment of the recording can be surely done while performing positioning with high precision.

[Second embodiment]

Next, the second embodiment according to the present invention is to be described.

Many points of the constitution of this embodiment are the same as in the first embodiment as described above. The different point is that a positioning means for performing positioning with still better precision is provided.

More specifically, this embodiment is an ink jet recording head having a discharge port for discharging ink and an energy generation means for generating energy for discharging ink, which is detachable relative to the mounting means for mounting the recording head onto the recording head of an ink jet recording means, characterized in that the recording head has a surface having the discharge port provided thereon, an electrical connecting terminal provided on a surface forming a specific angle with respect to the surface and a rotation center portion in attachment and detachment relative to the mounting means of the recording head, the center axis of the rotation center portion is substantially parallel to the surface where the discharge port is provided and the surface where the connecting terminal is provided, with its position being made on the side opposed to the connecting terminal with respect to the surface where the discharge port is provided and outside the range where the discharge port is provided, and on the discharge port side relative to the connecting terminal near the surface side where the discharge port is provided, and further has a positioning member provided between the discharge port and the connecting terminal.

Further, it is an ink jet recording device, comprising an ink jet recording head having a discharge port for discharging ink and an energy generation means for generating energy for discharging ink, wherein the recording head has a surface having the discharge port provided thereon, an electrical connecting terminal provided on a surface forming a specific angle with respect to the surface and a rotation center portion in attachment and detachment relative to the mounting means of the recording head, the center axis of the rotation center portion is substantially parallel to the surface where the discharge port is provided and the surface where the connecting terminal is provided, with its position being made on the side opposed to the connecting terminal with respect to the surface where the discharge port is provided and outside the range where the discharge port is provided, and on the discharge port side relative to the connecting terminal near the surface side where the discharge port is provided, further having a positioning means provided between the discharge port and the connecting terminal, and a mounting

means having a member engaged with the positioning member for mounting the recording head.

Referring now to the drawings of Figs. 9 through 14B, one embodiment of the present invention is to be described specifically and in detail.

Fig. 9 is a schematic perspective view of appearance showing the principal part of the recording device. Fig. 10A is a schematic perspective view of the recording to the embodiment of the present invention as viewed from the bottom side, Fig. 10B is a schematic plan view of the recording head according to this embodiment, Fig. 11A is a schematic perspective view of the carriage according to this embodiment, and Fig. 11b is a schematic plan view of this embodiment as viewed from above.

First, in Fig. 9, the carriage 20 as the mounting means having the recording head 10 mounted thereon moves along the paper delivery roller 60 as guided by the guide shaft 40. Recording head 10 discharges ink toward the surface of the recording paper P as the recording medium, thereby forming an image with the attached ink droplets to effect recording. 30 is the discharge restoration means located at the home position of the carriage 20. The discharge restoration means is constituted of a cap 31 comprising an elastic material such as rubber, etc. provided for protecting the discharge port by covering over the discharge port and also preventing ink from depositing by prevention of drying of the discharge port vicinity including the discharge port, and a suction pump 33 communicated to the cap 31 through an elastic tube 32. By sucking ink and/or air through the discharge port by reducing the internal pressure of the cap 31 with the pump 33, the discharging state of ink can be made good. The carriage 20 is located at the home position as the non-recording position except when the recording head 10 performs recording, so that the discharge port may be protected there with the cap 31. And, the constitution is made so that attachment and detachment of the recording head 10 may be performed necessarily at the home position. The above-mentioned constitution is the same as in the first embodiment.

Next, by referring to Figs. 10A and 10B, the constitution of the recording head 10 is described. In these Figures, the recording head 10 of the ink tank integration type is equipped with a recording head element 10c provided with an electrothermal transducer not shown as the energy generation means for generating thermal energy as the energy to be utilized for discharging of ink. As the energy generation means to be employed for such recording head element, otherwise a piezoelectric element, etc. can be also employed. However, the constitution by use of the electrothermal transducer as mentioned above having the advantages

of simple constitution, lowered production cost and possibility of high densification may be preferably utilized.

10a is a connecting terminal for transmitting the recording signal (electrical signal), 10b a guide pin which becomes the rotation center of the recording head 1 during attachment and detachment relative to the carriage by fitting to the carriage 20 as described below. The recording head element 10c is provided with a plurality of ink discharge ports 10d on the front surface. The connecting terminal 10a is provided with a concavity 10f which is a portion recessed by about 1 to 2 mm toward inside with longitudinal length $X = 35$ mm and lateral length $Y = 10$ mm for preventing contamination with ink, etc. and deformation, etc. of the connecting terminal 10a by touching with hands during handling. Behind the recording head is provided a fixing hook 10g (see Fig. 6A) for fixing the recording head through engagement with the nail portion of the carriage 20. And as the characteristic point of this embodiment, a rib 11 as the positioning member is provided on substantially the straight line connecting the ink discharge port 10d and the connecting terminal 10b. The rib 11 performs positioning through engagement of the positioning member of the carriage 20 as described later.

Referring now to Figs. 11A and 11b, the constitution of the carriage 20 is described. In these Figures, 20a is the connecting terminal bonded to the connecting terminal 10a on the carriage side of the recording head 10, 20b the fitting portion fitted to the guide pin 10b of the recording head 10, 20c the connecting terminal 10a, 20a the elastic member for giving an adequate pressure contact force (20 to 50 g per one terminal) during bonding of the 20a, for which chloroprene rubber, urethane rubber, molybdenum rubber, etc. may be used as preferable material for having optimum modulus of elasticity. 21 is a positioning member formed at the concavity for effecting positioning through engagement with the positioning rib 11 of the recording head 10. The positioning member on the inserted side is tapered as shown in Fig. 11b, 22 is a plate spring provided to take balance with the pressure forces of connecting terminals 10a, 20a, and has the hop-up function during dismantling of the head as described below. 23 is engaged with the fixing hook 10g of the recording head 10 to fix and hold the recording head 10. 50 is a flexible cable for transmitting electrical signals from the recording control section not shown to the connecting terminal 20a of the carriage.

The mounting method of the recording head in the constitution as described above is described in detail by referring to Figs. 12A, 12B, 12C and 12D.

Fig. 12A shows the state of mounting initiation

state, Fig. 12B the first state in the course of mounting, Fig. 12C the second state in the course of mounting and the Fig. 12D the state on completion of mounting.

First, as shown in Fig. 12A, when the recording head 10 is placed on the carriage 20, the guide pin 10b of the recording head and the carriage 10 at the bottom of the recording head are guided by the guide surface 20h and the tip end 20t of the lock lever 20i, and moves readily in the direction A in the Figure by the weight of the recording head 1. Next, as shown in Fig. 12B, when the guide pin 10b is fitted into the fitting portion 20b, the rear end portion of the recording head 10 comes off from the lock lever 20i, to rotate the guide pin 10b in the direction C with the guide pin 10b as the center, whereby the fixing hook 10g comes against the lock lever as shown in Fig. 12C. At this time, for positioning of the recording head 10, the side face 11a of the rib 11 (Fig. 10B) begins to be fitted into the inside face 21a (Fig. 11b) of the positioning member 21 of the carriage 20 to effect positioning in the direction x in Fig. 11B.

Next, when the rear end of the recording head 10 is compulsorily pushed up in the direction D in Fig. 12C, the discharge port surface from the state as shown in Fig. 12C contacts little by little from its upper portion the elastic portion of the cap 31. Then, the connecting terminals contact successively from the discharge port side, then the pads of connecting terminals 10a, 20a successively from the discharge port side, until finally the fixing hook 10g is hooked by the nail portion 23 of the lock lever 20i to become the state held by fixing as shown in Fig. 12D, whereby the connecting terminals 10a and 20a are correctly connected electrically and mechanically. At this time, the discharge port is also surely capped. At this time, the front surface 11b of the positioning rib 11 of the recording head and the inner rear surface 21b of the positioning member 21 of the carriage 20 come against each other, whereby the positioning in the direction y in Fig. 11B is effected (see Figs. 10B, 11b).

In the constitution capable of performing the actuation as described above, since the guide pin 10b, namely the rotation center of the recording head 10 is provided within the range PC in Fig. 12D upwardly of the position corresponding to the cap and in front of the position PT of the connecting terminal, the front surface (namely discharge port) and the cap 31 of the recording head element 10c, and the connecting terminals 10a and 20a are adequately contacted or connected with each other without interference with other portions.

Further, by slight rubbing mutually between the connecting terminals during mounting of the recording head 10, foreign matters existing on the

terminal surface can be also shaven off or scraped off to give the action of effecting surely electrical connection.

This manner is described in more detail by referring to Figs. 13A to 13E, 14A and 14B. Fig. 13A through 13E show the manner in which the connecting terminals are bonded to each other. Figs. 14A and 14B are schematic illustrations partially enlarged of one of a plurality of electrode pads as unit elements of connecting terminal, showing the states at the beginning of contact and on completion of connection.

The plural number of electrode pads 13 of the connecting terminal 10a of the recording head 10 of this embodiment are made of lead frame of metal, etc., with the contact points being made flat. The plural number of electrode pads 24 of the connecting terminal 20a of the carriage 20 are worked into semispherical projected shapes by application of plating to the terminal on the flexible cable 50. Corresponding to the mounting actuation of the recording head, first the electrode pads from the discharge port side will contact from the state in Fig. 13A as shown in Fig. 13B, and successively as shown in Fig. 13C. In transferring from Figs. 13B to 13E, the pads are rubbed mutually one to one to maintain good electrical contact.

The pressure contact force at the contact point of the pad is controlled through deformation of the elastic member 20c, whereby superfluous contact force can be absorbed to give adequate pressure contact force. When mounting of the recording head is completed, as shown in Fig. 13E, the position of the connecting terminal 20a of the carriage is positioned lower than the position in Fig. 13A, whereby the pressure contact force is applied upwardly with the elastic member 20c. Such pressure contact force is balanced with the forces of the nail 23 and the fitting portion 20b of the carriage. Further, connection of the terminal is described in detail by referring to Figs. 14A and 14B. In Figs. 14A and 14B, I shows the contact position of the electrode pad 12 at the beginning of contact, and J the contact position of the electrode pads 13, 24 under the final state. Through the slippage k between the contact points, even when foreign matters may be adhered on the contact point terminal surface, they can be scraped off to effect sure electrical connection. For connection as described above ($k > 0$) to be effected, the constitution is required to be made such that the rotation center as the standard for rotation should be positioned with a predetermined distance in the direction of the normal line 13-2 of the contact portion of the electrode pad 13 of the recording head from the tangential line 13-1 of the contact portion, and also the electrical pad 24 of the carriage 20 should be dislocated ($m > 0$) when the head 10 is moun-

ted.

Next, the method for dismantling the recording head 10 is to be described.

First, when the lock lever 20i is moved by pressing in the direction EJ in Fig. 12D, the fixing hook 10g is disengaged from the nail 23 to release fixing of the recording head 10. Then, by the plate spring 22 provided for taking balance with the connecting terminals 10a, 20a, the rear portion of the recording head is hopped up through elastic force, and can be readily taken out.

Further, in the above-described embodiment of the present invention, the ink discharge port 10d, the positioning rib 11, the electrical connecting terminal 10f are all provided so as to be overlapped at least a part of the respective elements on substantially one straight line in the recording head element 10c, the positional relationships of the three elements can be held with high precision. Also, in the present embodiment, further the above three elements are provided on one end side where the recording head is located, and further the cap is located on the above straight line in the home position. According to this constitution, the positioning member for carriage and electrical connecting terminals can be arranged on one side of the recording head and the carriage, whereby an extremely advantageous constitution in aspect of practical armoring such as withdrawing of flexible cable, etc. is given, and also unsure capping due to positional slippage can be prevented to make the probability of breaking of the recording head and the cap accompanied with mounting actuation of the recording head very lower.

As described above, according to the mounting method of the first embodiment of the present invention, there is no breaking by way of rubbing of connecting terminals than is necessary and the recording head will receive no bad influence from outside, and the recording head can be positioned to the correct position of the carriage.

Further, the ink discharge port of the head, the positioning member and the electrical connecting member can be arranged in this order on substantially straight line, whereby attachment and detachment of the recording head can be done simply and surely, while positioning the position of the ink discharge port and the position of the electrical connecting terminal relative to the carriage with high precision.

Thus, by one actuation of mounting of the recording head, at least the three operations of positioning of head, electrical connection, capping can be completed.

Also, in the above second embodiment, the cap, the positioning rib and the connecting terminal are on substantially straight line. That is, they are not completely coincident on one straight line, but

a part of the respective elements are deviated from the straight line, but of course they can be made coincident with each other.

[Third embodiment]

In the first and the second embodiments as described above in detail, description has been made about the mounting actuation accompanying the rotational actuation from the upper direction to the lower direction as the direction (yz) crossing the moving direction of the carriage.

In this third embodiment, in addition to the rotational actuation in the direction (yz) as mentioned above, rotational actuation within the plane (xy) in parallel to the moving direction of the carriage. And, as the joining actuation of the connecting terminal, as different from the above first and second embodiments, rotation within a plane in parallel to the moving direction of the carriage is utilized.

Such actuations would be readily understood by addition of geometrical considerations.

Thus, still more protection of the connecting terminal can be effected, and also protection of the positioning member can be strengthened.

Also, in this third embodiment, as different from the first and the second embodiments, since two rotational actuations are accompanied, no rotation center as shown in the first and the second embodiments is provided. However, it is a constitution for accomplishing the object of the present invention, and can invariably exhibit the effect for that purpose and is of course included within the category of the present invention.

In the following embodiments, the first constitution of the present invention is that, in an ink tank integrated type recording head detachable relative to an ink jet recording device, the head has a recording portion for ink discharging protruded forwardly from the ink tank and a positioning portion of the recording portion relative to the recording device, with the positioning portion being positioned inside of the boundary of the space formed by the boundary comprising connection mutually between the ends on the side where the recording portion is positioned and the outer surface of the recording head.

Alternatively, it is made such that in an ink tank integrated type recording head detachable relative to the ink jet recording device, the head has an ink tank, a recording portion mounted onto the ink tank, the recording portion having a base plate adhered to the ink tank and a plurality of regions for positioning of the element recording portion provided on the base plate itself, with the positioning regions being made the positioning portions of

the ink tank integrated type to the main body of the recording device.

Further, it is made such that in an ink tank integrated type recording head detachable to the carriage of the ink jet recording device, the head has an electrode portion which receives driving signals from the main body of the device by electrically connecting to the power supplying portion provided on the carriage for mounting the main body, a positioning portion, which is provided around the recording portion held integrally with the recording head, for positioning the recording portion of the recording head into the carriage through engagement with the receiving portion for positioning on the carriage, and an impeding portion for impeding electrical connection of the electrode portion with the power supplying portion and also impeding engagement of the positioning portion with the receiving portion for positioning through sliding with the carriage, the above electrical connection and the above engagement being made tolerable when the impeding portion becomes a concavo-convex engagement with the carriage.

Further, it is made such that in a carriage of an ink jet recording device for mounting a detachable ink jet recording head, the carriage has a receiving portion for receiving the positioning on the recording portion side provided on the recording head, a protruded portion inserted into the concavity of the recording head and equipped with a power supplying portion to be connected electrically to the electrode portion within the concavity, a sliding portion which inhibits engagement of the positioning portion with the receiving portion for positioning and also impeding electrical connection by sliding relatively with the recording head for mounting of the recording head, an engaging receiving portion which affords engagement of the positioning portion with the receiving portion for positioning and electrical connection through concavo-convex engagement with the recording head, and a holding means for maintaining the mounting position of the recording head.

Further, it is made such that in an ink jet recording device equipped with a cap for covering over the recording portion of the head through adhesion to an ink jet recording head, the device has a carriage having a mounting position for mounting the ink jet recording head at the position opposed to the above cap, a guide portion for guiding the recording head while maintaining a gap between the cap and the recording portion, so as to prevent contact of the recording portion of the recording head with the cap, in mounting the ink jet recording head onto the carriage in the position, a concavo-convex engaging portion to the recording head existing on the extended line from the guide portion which affords adhesion of the recording

portion to the cap substantially simultaneously with mounting of the recording head on the recording head positioning region of the carriage, and a recording head holding means equipped with an elastic portion which ensures concavo-convex engagement by imparting an elastic force.

In the prior art, an exchangeable, detachable type recording head (recording head cartridge) had a positioning portion at the position which is outer surface of the cartridge, including the end, and therefore damaging or attachment of dust, etc. sometimes occurred by falling, whereby the inherent positioning portion may come out of order.

However, according to the present invention, since the positioning portion is formed within the space where the positioning portion can be positively protected, and therefore it has become possible to effect positioning correctly even if inconveniences in operation may occur to cause falling or end contamination to occur.

Also, in integration of the ink tank and the recording head, the positioning of the cartridge to the main body has been effected with the ink tank as the center, and in addition, one which also effects positioning of the recording head itself, or one having further the positioning portion of the recording head added has been considered. However, while these proved to be poor in precision, in the present invention, since also the positioning of the cartridge of the cartridge and the recording portion of the recording head is performed relative to the base plate of the recording head, positioning with high precision can be accomplished.

Further, according to the present invention, damaging of the positioning portion, the electrode portion of the cartridge during attachment and detachment can be reduced to great extent, whereby damaging of the carriage itself relative to the cartridge can be prevented to great extent. As the result, the positioning precision can be improved to great extent. Since the electrode is located within the concavity, there is the electrode protection effect, and also lowering in positioning precision with dust, etc. attached on the electrode can be prevented.

In addition, according to the present invention, the discharge function of the head can be maintained by ensuring quickly the capped state during cartridge mounting, while preventing damaging of the cap and the head.

Those corresponding to the above expressions and the constitutions as described in the embodiment of the present inventions are included in the present invention. In the concavo-convex engagement (portion) in the above-mentioned constitutions, all embodiments are included in the present invention, provided that one is convexity, the other is concavity or a combination of both. Also, the

present invention is inclusive of all combinations with any desired constitution of the above technical thoughts.

Referring now to the drawings, the present embodiment is described specifically and in detail.

Fig. 15 is a schematic perspective view of the ink jet recording device (ink jet printer) according to the embodiment of the present invention. Fig. 16A is a schematic perspective view of an ink tank integrated type recording head cartridge (recording head) to be mounted on the printer as viewed from the bottom side, Fig. 16B is a schematic perspective view of the same as viewed from the top side, Fig. 16C is a schematic bottom view of the same, and Fig. 17 is a schematic sectional view of the same. Fig. 18A is a schematic perspective view showing a constitutional example of the carriage as the mounting member for mounting the recording head, Fig. 18B and Fig. 18C are respectively a schematic top view and a schematic back view of the same.

By use of these Figures, the outline of the embodiment of the present invention is described.

First, in Fig. 15, the carriage 20 having the recording head 10 mounted thereon is guided along the paper delivery roller 60 by the guide shaft 70, the recording head 10 discharges ink toward the surface of the recording paper P as the recording medium, and forms an image with the attached ink droplets, thereby performing recording. 30 is the discharge restoration means located at, for example, the home position of the carriage 20. This is constituted of a cap 31 comprising an elastic material such as rubber, etc. provided for protecting the discharge port by covering over the discharge port and also preventing securing of ink by prevention of drying of the discharge port vicinity including the discharge port, and a suction pump 33 communicated to the cap 31 through an elastic tube 32. And, by sucking ink and/or air through the discharge port by reducing the pressure internally of the cap 31 with the pump 33 to remove factors for causing defective discharge such as thickened ink, bubbles, etc., whereby the discharging state of ink can be made good. The carriage 20 is located at the home position as the non-recording position except when the recording head 10 performs recording, so that the discharge port may be protected there with the cap 31. And, in this embodiment, the constitution is made so that attachment and detachment of the recording head 10 may be performed necessarily at the home position. The above constitution is substantially the same as in the first and the second embodiments as described above.

Next, by referring to Figs. 16A through 16C and Fig. 17, the constitution of the recording head is described. In this embodiment, the recording

head is constituted of a recording head element 311 and an ink tank 312 which are integrated.

Here, the recording head element 311 is provided, as the energy generation means for generating the energy to be utilized for discharging ink, with a discharging portion 311d having an ink discharge port on the front surface by use of an electrothermal transducer in the form which acts thermal energy on ink corresponding to current passage. As the energy generation means, otherwise an electromechanical transducing element, etc. can be also employed. However, the constitution is made in this embodiment by use of an electrothermal transducer, because the preparation steps are simple, the production cost is low and also high density integration of discharging ports or liquid channels communicated thereto can be effected, and a plurality of discharging ports and liquid channels communicated thereto are provided, with arrangements of electrothermal transducers in the respective liquid channels.

311e is a connecting terminal having the electrode portion for supplying electrical signals to the electrothermal transducer, and in this embodiment, for example, it has dimensions of $X = 30$ mm and $Y = 10$ mm in Fig. 16A and arranged within the head element housing portion 310a opened on the recording head 10 side, whereby contamination of the connecting terminal 311e with ink, etc., occurrence of damage, abrasion, deformation, dust attachment by touching with hands of the operator during handling, breaking of the electrothermal transducer by electrostatic charges are further prevented. This positional relationship is different from the embodiments in the foregoing first and second embodiments. 310b is a guide member as the sliding portion which becomes the guide in mounting the recording head 10 onto the carriage 20, and in this embodiment the extended length is made $L = 3$ mm (see Fig. 16C). 310c is a fixing pin which forms the auxiliary projection for positioning receiving the urging force for fixing the recording head by engagement with the fixing lever 340 provided rotatably on the carriage 20 as described later by referring to Figs. 18A to 18C. This pin may be also provided behind the base plate 313 integrally therewith, and with such constitution, further precision can be ensured.

310d, 310e and 310f are positioning portions which form the respective standard faces in the x direction, y direction and z direction crossed perpendicularly to one another in Figs. 16A to 16C, for fixing the recording head 10 to a predetermined position of the carriage 20 by contacting the standard face of the carriage 20.

The respective faces 310d, 310e and 310f in these x, y and z directions are provided integrally on the base plate 313 which forms the supporting

member of the discharging portion 311d of the recording head 10, which are arranged substantially linearly to ensure readily precision in production. Also, these are provided at the position which hands, etc. of the operator can hardly touch during handling as described later, namely below the discharging portion 311d, whereby damage, deformation, dust attachment will occur with difficulty. Further, by provision of these standard faces on the base plate 313 nearby the discharging portion 311d, the positioning precision of the discharging portion 311d during mounting onto the carriage 20 can be well ensured. More specifically, in this embodiment, by providing the positioning portions 310d to 310f inside of the boundary of the space formed by the boundary obtained by connecting mutually the ends on the side where the discharging portion 311d is positioned (a - g, j in Figs. 16A, 16B), it becomes possible to effect positioning accurately even if falling or contamination may occur because of inconveniences in operation. The base plate 313 can be formed of, for example, aluminum, etc. and has the function of dissipating heat as the heat dissipating plate for inhibiting temperature elevation of the recording head 10 accompanied with driving of the electrothermal transducer. The upper and lower portions forming the standard face 310d (see Fig. 16B) are to regulate the slanting of the recording head 10, and the span (interval) should be preferably 15 mm or longer in this embodiment, and hence it was made 16 mm in this embodiment. However, this can be selected to an adequate value depending on the size of the device. Also, if regulation of the slanting poses no problem, the standard face 310d may be also one.

Referring to Fig. 17, for introducing ink from the ink tank 312 to the recording head element 311 side, the communication pipe 311a penetrates internally through the feeding inlet 312k of the ink tank 312. Also, the introducing inlet at its tip end is provided with a filter 311d, whereby penetration of bubbles, etc. from the ink tank 3110 is impeded.

In connecting the head element 311 and the ink tank 312, the head element 311 is mounted to the ink tank 312 in the direction shown by the arrowhead A in Fig. 17. At this time, the wall portion provided with the opening 312b of the ink tank 312 is expanded toward outside as accompanied with engagement of the projection 311b provided on the head element 311 with the tapered surface, and simultaneously the communication pipe 311a is penetrated into the feeding inlet 312k.

And, when the projection 311b and the opening 312b reach the positions where they are completely opposed to each other, the wall portion is restored to the original position through its spring characteristic, and the projection 311b is fitted into

the opening 312b to obtain the mounted state as shown in Fig. 17. On the other hand, the communication pipe 311a becomes the state with the introducing inlet at its tip end pressure contacting the absorber 312a impregnated with ink, whereby good ink communication can be obtained. In Fig. 17, 312m is an O ring as the sealing material which ensures ink sealing at the feeding inlet 312k portion.

According to the constitution as described above, only by pushing the head element 311 relative to the ink tank 312 in the direction shown by the arrowhead A in Fig. 17, connection of the both can be effected without requiring any step such as adhesion, etc. Also, since the communication pipe 311a provided on the head element 311 side is permitted to penetrate into the ink tank 312 so that its tip end may pressure contact the ink absorber 312a, whereby the ink communication can be ensured.

In the constitution as described above, the projection 311b is provided on the head element side, and also the opening 312b provided on the wall portion of the ink tank 312 so as to effect engagement between the projection 311b and the opening 312b by utilizing flexibility or elasticity of the wall portion in mounting, but the constitution at this portion can be determined as desired. For example, in place of forming the wall portion with flexibility, even if this may be slightly rigid, the constitution may be made such that the projection 311b is supported with a spring, etc. so as to be urged in the direction projected outwardly and fitted into the opening 312b through the urging force of the spring when the projection 311b is retreated inwardly accompanied with the mounting actuation as described above and opposed to the opening 312b.

Whereas, in this embodiment, since the head element 311 is constituted to have a base plate 313 extending relatively longer integrated therewith, the mounting actuation including positioning can be made easier by utilizing this portion, and the mounted state can be made surer.

Referring again to Fig. 16C, in this embodiment, the face of the abutting member 312c arranged on the element housing portion 310a of the ink tank 312 against which the rear end brim 313c of the base plate 313 is abutted is formed to a tapered surface. And, in the abutted state as shown, registration between the projection 311b and the opening 312b or registration between the communication pipe 311a and the opening 312k is effected.

Thus, in mounting the head element 311 onto the ink tank 312, by first abutting the rear end brim 313c of the base plate 313 against the tapered face of the abutting member 312c, and performing the

actuation as described above by referring to Fig. 17 under this state, it becomes possible to effect connection between the head element 311 and the ink tank 312. Also, since not only joining can be effected by fitting of the projection 311b into the opening 312b, but also the rear end side 313c of the base plate 313 can be pushed against the ink tank by the tapered face of the abutting member 312c, the mounted state can be made surer.

Further, employment of such constitution of the abutting portion is advantageous with respect to working precision and with respect to difficulty of occurrence of the position disturbance with burr, as compared with the case of forming this in a right angle hook form.

Next, by referring to Figs. 18A through 18C the constitution of the carriage 20 according to this embodiment is described.

In these Figures, 320a is a connecting terminal which is the power supplying portion bonded to the connecting terminal 311e of the recording head 10, 320b is the guide rail which forms the sliding portion for guiding the guide member 310b during mounting of the recording head 10 to guide the recording head to a predetermined position. 320c is an elastic member for giving an appropriate pressure contact force (e.g. 20 to 50 g per 1 pad) during bonding of the connecting terminals 311e and 320a, for which chloroprene rubber, urethane rubber, moltprene rubber etc. may be preferably used for having appropriate modulus.

340 is the fixed lever for performing the operation to fix the head 10 to the carriage 20, and axially supported rotatably on the carriage 20 by the shaft 341. And, the fixing lever 340, at the fixing position of the recording head 10 (the position of 340(A) shown by the solid line in Fig. 18C), pushes the fixing pin 310c provided on the recording head 10 in the direction C in Fig. 18C with the pressing face 340a of the portion 3402, and similarly in the direction D with the pressing face 340b of the portion 3402, thereby urging the recording head 10 against the fixing position. Also, during mounting, the recording head 10 is pressed in the direction E in Fig. 18B with the lower side brim 340c of the fixing lever 340. 3401 is the portion for fixing the lever 340 to the carriage during head mounting.

320d, 320e and 320f are positioning receiving portions which form the respective standard faces for positioning the recording head on a predetermined position on the carriage 20, and become the positioning standards in the x direction, y direction and z direction. That is, positioning in the x direction is effected by contacting of the x direction standard face 320d of the carriage 20 with the x direction standard face 310d provided on the base plate 313 of the recording head 10. Similarly, the positioning in the y direction is effected by contact-

ing of the y direction standard face 320e of the carriage 20 with the y direction standard face 310e of the recording head 10, and the positioning in the z direction by contacting of the z direction standard face 320f of the carriage 20 with the z direction standard face of the recording head 10.

320g is the pressing portion for pressing the recording head 10 for contacting of the y direction standard faces 310e and 320e. 320h is the pressing portion for pressing the recording head 10 for contacting of the z direction standard faces 310f and 320f, which forms the engagement receiving portion.

In Fig. 18A, 50 is a flexible cable to be used for transmitting driving signals from the control circuit of the device main body to the recording head 10, etc.

Mounting actuation of the recording head 10 onto the carriage 20 is described primarily with respect to the y direction and the z direction by use of Fig. 19 and Fig. 20.

First, the recording head 10 is set at a predetermined position on the carriage 10 where the guide member 310b is guided by the guide rail 320b, and mounting is begun from this position (the position of 310(a) in Fig. 19).

In this embodiment, mounting actuation is done at the home position where the discharge port surface is opposed to the cap 31, but at this time, a predetermined distance (2 mm in this embodiment) is ensured between the discharge port surface 310i of the recording head 10 and the cap 31 with extension $L=33$ of the guide member 310b (see Fig. 16C), whereby the inconvenience of contacting of the recording head 10 with the cap 31 can be prevented.

As the recording head 10 is slid downward under the state with the guide member 310b being guided by the guide rail 320b, the recording head 10 is mounted to the position shown by 310(b) in Fig. 19. At this time, the rear end side of the recording head 10 becomes the state stopped by engagement at the upper end of the pressing portion 320g, whereby further mounting is once impeded.

When the fixing lever 340 is operated from the position of 340(B) shown by the broken line in Fig. 18C to the position of 340(A), the recording head 10 is pushed out in the E direction in Fig. 19 (y direction) with the pressing force P_3 (see Fig. 18B) given by the lower side brim 340c of the fixing lever 340, and also pushed down in the direction D in Fig. 18C with the pressing force of the pressing face 340b. By this, the rear end of the recording head 10 comes beyond the pressing portion 320g to be set at the position shown by 310(C) in Fig. 19, thus completing the mounting actuation of the recording head 10.

At this time, as shown in Fig. 19 and Fig. 20, on the recording head 10 acts the force P_1 from the tapered portion of the pressing portion 320h through the guide member 310b to press the recording head tip end portion elastically toward the carriage bottom side. Also, the force P_1' acts from the front surface toward the rear end (see Fig. 18B), and also the force P_2 acts from the pressing portion 320g through the recording head rear end side, whereby the recording head 10 is pressed elastically toward the cap 31 side. By this, the y direction standard face 310e of the base plate 313 of the recording head 10 and the z direction standard face 310f, the y direction standard face 320e of the carriage 20 and the z direction standard face 320f come into contact, respectively, whereby positioning with respect to the y direction and the z direction of the recording head 10 is effected.

Next, the mounting actuation of the recording head 10 onto the carriage 20 is described primarily with respect to the x direction by use of Figs. 21A and 21B, and Figs. 7A to 7C.

As shown in Fig. 21A, as accompanied with the operation of the fixing lever 340, its pressing face 340a is engaged with the fixing pin 310c, to act urging force in the c direction. On the other hand, on the fixing pin 310c acts the force in the D direction with the pressing face 340b (see Fig. 18C) and also the force in the E direction acts from the rear end of the recording head 10. By the action of the force in the E direction, the recording head 10 moves in the y direction, as shown in Fig. 21(B) whereby the portion of the base plate 313 provided with the positioning standard face 310d in the x direction comes beyond the tapered face 320d of the portion provided with the positioning standard face 320d of the carriage 20, thus effecting positioning in the x direction of the recording head 10 through opposed contact of the both standard faces 310d, 320d on completion of mounting.

At this time, since the force acts on the recording head 10 from the carriage 20 side through the fixing pin 310c and the x direction standard face 310d, the terminals end 311e and the 320a come into contact under pressed state.

Here, the process reaching connection between the connecting terminals 311e and 320a is described by use of Figs. 22A to 22C. The states 22[A] to 22[C] in the Figures correspond to the respective states 310[a] to 310[c] of the recording head 10 in Fig. 19.

First, in the process reaching from the state of 310(a) to the state of 310[b] in Fig. 19, the terminals 11e, 20a are in the positional relationship shown by 310[a] in Figs. 22A to 22C, and are not in contact with each other.

As the process from the state 310[B] to the state 310[C] in Fig. 19 proceeds, namely as the

fixing lever 340 is operated, the state becomes as shown in Fig. 22B, whereby the terminals 311e, 320a begin to come into contact with each other. At the same time, the terminal 311e slides on the terminal 320a in the same direction, as accompanied with the movement of the recording head 10 in the E direction. Therefore, in this process, even if coating or foreign matter due to ink contamination may exist or protective film may be provided, these can be scraped off to refresh the contact surface. Also, since said sliding is performed mutually one to one corresponding pads in the vicinity of their connected position, the risk of damaging terminals can be markedly reduced.

And, when mounting is completed as shown by 310[c] in Fig. 19, the terminals 311e, 320a become the state as shown in Fig. 22C, whereby good connected state is obtained at the predetermined position.

Also, the discharging surface of the discharge portion 311d is bonded for the first time to the cap 31, whereby damaging of the both during mounting process can be prevented, and quick protection of the discharging surface after mounting can be effected.

As described above, according to this embodiment, in connecting the connecting terminals, electrical connection can be effected with the optimum force without damaging terminals, and which can refresh their surfaces, and also it becomes possible to mount the recording head including said connection by way of simple actuation, and yet sure positioning and protection of the discharge portion can be also done on completion thereof.

Claims

1. An ink jet recording device equipped with:
a recording head having a discharge port for discharging ink, an energy generating element for generating ink through said discharge port, and a first electrical connecting terminal; and
a carriage provided with a second electrical connecting terminal for mounting said recording head thereon,
wherein the mounting actuation of said recording head onto said carriage includes rotation of said recording head, and a plurality of unit elements of said first electrical connecting terminal and a plurality of unit elements of said second electrical connecting terminal are coupled while being rubbed one to one with each other during the mounting actuation of said recording head.

2. An ink jet recording head according to Claim 1, wherein said first connecting terminal is provided on the surface different from that on which said discharge port is provided.

3. An ink jet recording device according to Claim 1, wherein said discharge port is provided in the front surface, and said first connecting terminal is provided at the bottom surface.

4. An ink jet recording device according to Claim 1, wherein said recording head has the discharge port at the portion protruded from the first surface, and said first connecting terminal arranged in the concavity of the surface crossed perpendicularly with said surface.

5. An ink jet recording device according to Claim 1, wherein said energy generating element is an electrothermal transducer.

6. An ink jet recording device according to Claim 1, wherein said recording head is a head which discharges ink by utilizing heat energy.

7. An ink jet recording device according to Claim 1, wherein said recording head has an ink tank for housing ink integrally therewith.

8. An ink jet recording device according to Claim 1, wherein said recording head has an ink tank for housing ink integrally therewith, and an ink absorber is arranged in said ink tank.

9. An ink jet recording device according to Claim 1, wherein said recording head has a discharging portion having an ink tank, a discharge port and an energy generating element, a base plate having said discharging portion arranged thereon, and a positioning portion formed on said base plate.

10. An ink jet recording device according to Claim 9, wherein said base plate has heat dissipating function.

11. An ink jet recording device according to Claim 1, wherein said recording head has a guide member for guiding said recording head during mounting of said recording head onto said carriage.

12. An ink jet recording device according to Claim 1, wherein said recording head has a projection for aiding positioning to receive the urging force for fixing said recording head on said carriage arranged thereon.

13. An ink jet recording device according to Claim 1, wherein said recording head has a positioning member which becomes the standard for effecting positioning relative to said carriage arranged thereon.

14. An ink jet recording device according to Claim 1, wherein said recording head has the discharge port arranged at the portion protruded from the front surface of the ink tank for housing ink arranged thereon, and the positioning portion is arranged between said front surface and the discharge port surface having said discharge port arranged thereon.

15. An ink jet recording device according to Claim 1, wherein said recording head has a concavity for performing positioning by engagement.

with the concavity of said carriage arranged thereon.

16. An ink jet recording device according to Claim 1, wherein a positioning member is arranged so that after positioning in the moving direction, the positioning may be effected in the direction crossed therewith.

17. An ink jet recording device according to Claim 1, wherein said positioning portion is arranged internally of a space which can positively protect said positioning portion.

18. An ink jet recording device according to Claim 1, wherein said positioning portion is arranged between a space formed between the boundary formed by connecting mutually the ends on the side where the discharge port is positioned in the recording head, and the outer surface on the discharge port side of the ink tank.

19. An ink jet recording device according to Claim 1, wherein the site which becomes the standard for rotation of said recording head is positioned on said discharge port side from said first connecting terminal and at the position on the opposite side with respect to said first connecting terminal with said discharge port sandwiched therebetween.

20. An ink jet recording device according to Claim 1, wherein the mounting actuation of said recording head is accompanied with rotation actuations in a plurality of directions.

21. An ink jet recording device according to Claim 1, wherein said rotation actuations include rotation from upward to downward, and rotation within a plane in parallel to the moving direction of the carriage.

22. An ink jet recording device according to Claim 1, wherein the mounting actuation of said recording head comprises the process of sliding said recording head downwardly by utilizing a guide member, and subsequently the process of moving it forwardly and also further downwardly by utilizing a fixing lever.

23. An ink jet recording device according to Claim 1, wherein the mounting actuation of said recording head is accompanied with forward movement by utilizing said fixing lever and also movement in the lateral direction during the process of further moving downwardly.

24. An ink jet recording device according to Claim 1, wherein the constitution is made so that the foreign matters attached on the connecting terminals can be removed by the mounting actuation of said recording head.

25. An ink jet recording device according to Claim 1, wherein the guide member arranged on the discharge port side of said recording head has the function of preventing of contact the discharge port with the cap in the course of the recording

head mounting actuation.

26. An ink jet recording device according to Claim 1, wherein the site which becomes the standard for rotation of said recording head is the rotation center.

27. An ink jet recording device according to Claim 26, wherein the constitution is made such that said rotation center is arranged at a position having a predetermined distance in the normal line direction of the contact portion from the tangential line of the contact portion of said connecting terminal, and said connecting terminal may be dislocated when the head is mounted.

28. An ink jet recording device according to Claim 1, wherein the constitution is made such that the mounting actuation of said recording head may be performed at the home position.

29. An ink jet recording device according to Claim 1, wherein said ink jet recording device has a cap for covering over said discharge port, and said discharge port is covered with said cap simultaneously with completion of mounting of said recording head.

30. An ink jet recording device according to Claim 1, wherein the site which becomes the standard for said rotation is provided at upper than the position corresponding to said cap and within the range forwardly of said connecting terminal.

31. An ink jet recording device according to Claim 1, wherein said carriage has a positioning member which becomes the standard for effecting positioning relative to said recording head arranged thereon.

32. An ink jet recording device according to Claim 1, wherein said carriage has a concavity having a tapered shape which becomes the standard for effecting positioning relative to said recording head arranged thereon.

33. An ink jet recording device according to Claim 1, wherein said second connecting terminal includes a terminal for supplying power to the discharging energy generating member of the recording head.

34. An ink jet recording device according to Claim 1, wherein said carriage has a member for applying force so as to dismantle the recording head.

35. An ink jet recording device according to Claim 1, wherein said carriage is provided with a plate spring as the member for applying force so as to dismantle the recording head.

36. An ink jet recording device according to Claim 1, wherein said carriage is provided with a member for applying force so as to hold said head by engagement with the recording head.

37. An ink jet recording device according to Claim 36, wherein the member for applying force so as to hold said head is a fixing lever.

38. An ink jet recording device according to Claim 1, wherein the unit elements of said second connecting member are arranged dislocatably on an elastic member.

39. An ink jet recording device according to Claim 38, wherein said elastic member is constituted of a material selected from chloroprene rubber, urethane rubber, moltiprene rubber.

40. An ink jet recording device according to Claim 1, wherein said discharge port, said first connecting terminal and the positioning member are arranged substantially linearly.

41. An ink jet recording device according to Claim 1, wherein said discharge port, said first connecting terminal and the positioning member are arranged on one side of the recording head.

42. An ink jet recording device according to Claim 1, wherein said discharge port, said first connecting terminal, the positioning member and the cap are arranged substantially linearly.

43. An ink jet recording head having a discharge port for discharging ink and an energy generation means for generating energy for discharging ink, which is detachable relative to the mounting means for mounting the recording head onto the recording head of an ink jet recording means, characterized in that the recording head has a surface having the discharge port provided thereon, an electrical connecting terminal provided on a surface forming a specific angle crossed with the surface and a rotation center portion in attachment and detachment relative to the mounting means of the recording head, the center axis of the rotation center portion is parallel to the surface where the discharge port is provided and the surface where the connecting terminal is provided, with its position being made on the side opposed to the connecting terminal with respect to the surface where the discharge port is provided and outside the range where the discharge port is provided, and on the discharge port side relative to the connecting terminal near the surface side where the discharge port is provided.

44. An ink jet recording device, comprising an ink jet recording head having a discharge port for discharging ink and an energy generation means for generating energy for discharging ink, wherein the recording head has a surface having the discharge port provided thereon, an electrical connecting terminal provided on a surface forming a specific angle crossed with the surface and a rotation center portion in attachment and detachment relative to the mounting means of the recording head, the center axis of the rotation center portion is parallel to the surface where the discharge port is provided and the surface where the connecting terminal is provided, with its position being made on the side opposed to the connecting terminal

with respect to the surface where the discharge port is provided and outside the range where the discharge port is provided, and on the discharge port side relative to the connecting terminal near the surface side where the discharge port is provided and

a mounting means having a site to be engaged to the rotation center for mounting the recording head.

45. A method for mounting a recording head having a discharge port for discharging ink, an energy generation means for generating the energy for discharge of the ink through the discharge port and an electrical connecting terminal provided on a surface forming a specific angle crossed with the surface where the discharge port is provided, characterized in that the recording head is mounted by engaging the rotation center portion having a center axis in parallel to both the surface where the discharge port is provided and the surface where the connecting terminal is provided and located on the side opposed to the connecting terminal with respect to the surface where the discharge port is provided, outside of the range where the discharge port is provided and on the discharge port side relative to the connecting terminal near the surface side where the discharge port is provided, to the site corresponding to the mounting means with the rotation center portion as the center.

46. An ink jet recording head having a discharge port for discharging ink and an energy generation means for generating energy for discharging ink, which is detachable relative to the mounting means for mounting the recording head onto the recording head of an ink jet recording means, characterized in that the recording head has a surface having the discharge port provided thereon, an electrical connecting terminal provided on a surface forming a specific angle crossed with said surface and a rotation center portion in attachment and detachment relative to the mounting means of the recording head, the center axis of the rotation center portion is substantially parallel to the surface where the discharge port is provided and the surface where the connecting terminal is provided, with its position being made on the side opposed to the connecting terminal with respect to the surface where the discharge port is provided and outside the range where the discharge port is provided, and on the discharge port side relative to the connecting terminal near the surface side where the discharge port is provided, and further has a positioning member provided between the discharge port and the connecting terminal.

47. An ink jet recording device having an ink jet recording head having a discharge port for discharging ink and an energy generation means for generating energy for discharging ink, wherein the recording head has a surface having the dis-

charge port provided thereon, an electrical connecting terminal provided on a surface forming a specific angle crossed with the surface and a rotation center portion in attachment and detachment relative to the mounting means of the recording head, the center axis of the rotation center portion is substantially parallel to the surface where the discharge port is provided and the surface where the connecting terminal is provided, with its position being made on the side opposed to the connecting terminal with respect to the surface where the discharge port is provided and outside the range where the discharge port is provided, and on the discharge port side relative to the connecting terminal near the surface side where the discharge port is provided, further having a positioning means provided between the discharge port and the connecting terminal, and mounting means having a member engaged with the positioning member for mounting the recording head.

48. An ink tank integrated type recording head detachable relative to an ink jet recording device, characterized in that the head has an ink discharging portion having an ink discharge port surface protruded forwardly from the ink tank and a positioning portion of the recording portion relative to the recording device, with said positioning portion being positioned inside of the boundary of the space formed by the boundary comprising connection mutually between the ends on the side where the recording portion is positioned and the outer surface of the recording head.

49. An ink tank integrated type recording head according to Claim 48, wherein said recording head has a base plate adhered to said ink tank by holding said discharging portion, and said positioning portion is provided only on said plate.

50. An ink tank integrated type recording head detachable relative to the ink jet recording device, characterized in that the head has an ink tank, a recording portion mounted onto the ink tank, said recording portion having an ink discharging portion having an ink discharge port surface, a base plate adhered to the ink tank and a plurality of regions for positioning said recording portion provided on said base plate itself, with said positioning regions being made the positioning portions of the ink tank integrated type to the main body of the recording device.

51. An ink tank integrated type recording head according to Claim 50, wherein the main body of the recording head comprises a molded product, said recording has an electrothermal transducer as the discharging energy generating element, said base plate is formed of a metal to have the function of dissipating heat.

52. An ink tank integrated type recording head

according to Claim 50, which has a projection for aiding positioning onto the main body of said recording device on the extension of said base plate.

53. An ink tank integrated type recording head detachable to the carriage of an ink jet recording device, characterized in that the head has an electrode portion formed on the concavity side surface of the main body of the recording head, and provided on the mounting means for mounting said main body which receives driving signals from the main body of the device by electrically connecting to the electrical connecting terminal of said mounting means, a positioning portion, which is provided around the recording portion having the ink discharge port surface held integrally with the recording head, for positioning the recording portion of the recording head onto said mounting means through engagement with the receiving portion for positioning on said mounting means, and an impeding portion for impeding electrical connection of the electrode portion with said electrical connecting terminal and also impeding engagement of said positioning portion with said receiving portion for positioning through sliding with said mounting means, said electrical connection and said engagement being made tolerable when said impeding portion becomes a concavo-convex engagement with said mounting means.

54. An ink tank integrated type recording head according to Claim 53, wherein said recording head has a base plate for holding said recording head, said positioning portion has the first and the second projections located at different positions with respect to the mounting direction of the main body of the recording head, and said recording position is held at a predetermined angle by positioning of said first and second positions onto said mounting means.

55. An ink tank integrated type recording head according to Claim 53, wherein said recording portion has an electrothermal transducer as the discharge energy generating element, said base plate is formed of a metal to have the function of dissipating heat, and said positioning portion is provided only on said base plate.

56. A carriage of an ink jet recording device for mounting a detachable ink jet recording head, characterized in that the carriage has a receiving portion for receiving the positioning on the recording portion side provided on said recording head, a protruded portion for electrode inserted into the concavity of said recording head and equipped with an electrical connecting terminal to be connected electrically to the electrode portion within the concavity, a sliding portion which inhibits engagement of the

positioning portion with the receiving portion for positioning and also impeding electrical connection by sliding relatively with said recording head for mounting of said recording head, an engaging receiving portion which affords engagement of the positioning portion with said receiving portion for positioning and electrical connection through concavo-convex engagement with the recording head, and a holding means for maintaining the mounting position of said recording head.

57. A carriage according to Claim 56, wherein said receiving portion for positioning and said electrical connecting member are adapted so as to act urging forces with different directions to said positioning portion and said electrode portion, respectively, under the mounted state of said recording head.

58. A carriage according to Claim 56, having an elastic portion which impedes temporarily the movement of said recording head relative to the direction in which the concavity of said recording head receiving said projection for electrode, and also acts an elastic force in the direction in which said positioning portion is engaged with said receiving portion for positioning when said recording head is urged in a direction different from said direction.

59. A carriage according to Claim 58, wherein said holding means has an operation lever for aiding mounting to perform said urging, and said operation lever has an engaging portion which is engaged with the end of said recording head to permit it to move in said different direction.

60. A carriage according to Claim 59, wherein said operation lever is positioned at the extended portion in the arrangement direction of said positioning portion and said electrode of said recording head to be mounted, and has an engaging portion which holds said recording head at a predetermined position through engagement with the projection provided on the opposite side to the portion of said recording where said positioning portion exists.

61. A carriage according to Claim 58, wherein said elastic portion has the function of engaging the relative sliding portion on the side of said recording head through its elastic force, and said holding means has a second elastic portion which maintains the concavo-convex engagement by imparting elastic force to said relative sliding portion.

62. An ink jet recording device equipped with a cap for covering over the ink discharge port of the head through adhesion to an ink jet recording head, characterized in that the device has a carriage having a mounting position for mounting the ink jet recording head at the position opposed to the above cap,

a guide portion for guiding the carriage while maintaining a gap between the cap and the recording portion having the ink discharge port arranged thereon in mounting the ink jet recording head onto the carriage in said position,

a concavo-convex engaging portion to the cartridge existing on the extended line from the guide portion which affords adhesion of the recording portion to the cap substantially simultaneously with mounting of the recording head on the recording head positioning region of the carriage, and a recording head holding means equipped with an elastic portion which ensures concavo-convex engagement by imparting an elastic force.

63. An ink jet recording device according to Claim 62, wherein said recording head holding means has an operation lever for aiding mounting of said recording head, said elastic portion is provided at the site which impedes the movement of said recording head to the positioning region, said operation lever imparts urging force for moving said recording head toward the cap, and affords the movement of said recording head by elastic deformation of said elastic portion corresponding to the movement of said recording head by said urging force.

64. An ink jet recording device according to Claim 62, wherein said carriage has an electrical connecting terminal provided by projection for joining by progressing into the concavity provided in said concavity, said the electrode portion provided in said concavity, said guide portion guides said electrode portion under electrically aperted state relative to said electrical connecting terminal, said concavo-convex engaging portion affords substantially simultaneously mounting of said recording head onto said positioning region, adhesion of said cap to said recording portion and electrical connection of said electrical connecting terminal to said electrode portion.

65. An ink jet recording device according to Claim 62, wherein said holding means impedes temporarily the movement of said recording head relative to the direction in which the concavity of said recording head receiving said projection for electrode, and also has an elastic portion which acts elastic force in the direction in which said positioning portion is engaged with said receiving portion for positioning when said recording head is urged in the cap direction different from said direction.

66. An ink jet recording device according to Claim 65, wherein said holding means has an operation lever for aiding mounting to perform said urging, and said operation lever has an engaging portion which moves said recording head in said different cap direction through engagement with the end thereof.

67. An ink jet recording device according to Claim 66, wherein said operation lever is positioned at the extended portion in the arrangement direction of said positioning portion of said recording head to be mounted and said electrode portion, and has an engaging portion which holds said recording head at a predetermined position by engagement with the projection provided on the opposite side to the portion of said recording head where said positioning portion exists.

68. An ink jet recording arrangement of the kind which includes a recording head which is detachably connectable to a carriage, the head and the carriage having electrical contacts which are brought together when the head is in its operative position on the carriage characterised in that the arrangement for mounting the head on the carriage is such that movement of the head into its operative position on the carriage involves pivotal and a small amount of translational movement whereby the latter movement slides the aforesaid electrical contacts in contact with one another to clean them.
